Molten Salts Data: Diffusion Coefficients in Single and Multi-Component Salt Systems

G. J. Janz and N. P. Bansal*

Molten Salts Data Center, Cogswell Laboratory, Rensselaer Polytechnic Institute, Troy, New York 12181

The property of diffusion is one of the basic properties of fluid systems. In molten salts, more than 700 studies have been reported to August, 1980, with more than 15 diffusion measurement techniques. A critical examination of these studies with a review of the techniques is presented. The results for more than 140 salt systems are reported in this communication as a series of data tables, with numerical values, value judgements, and literature citations. Silicates, slags, and oxide melts are excluded.

Key words: diffusion; diffusion coefficients; diffusion techniques; fused salts; molten salts; self-diffusion coefficients.

1. Introduction

The property of diffusion is one of the basic transport properties of fluid systems; and as such is important to various theoretical and practical considerations in materials science and technology.

The diffusion data for molten salts are largely in the primary scientific literature, and are thus rather widely dispersed (more than 100 journals) and not readily accessed. Our survey showed that more than 700 diffusion studies had been reported to date (1980), and that some 15 different measurement techniques had been applied. The need for a review of the diffusion data for molten salts was thus clearly apparent. In the present work we report the results of such a study. Silicates, slags and oxide solvent systems have not been included in the present work.

For closely related publications in this series, see [1-9]¹ and table 1.

2. Symbols and Units

The fundamental constants, symbols and units used in this work are in tables 2 and 3 respectively.

3. Statistical Analysis

The recommended data values were selected on the basis of our estimates of precision and accuracy of the data in

the literature.

All calculations were made on the digital computer facilities at Rensselaer Polytechnic Institute. The data of each recommended study, were fitted by a one-dimensional analysis, using the method of least squares, to establish the variation of the physical quantities with temperature at the experimental compositions.

The criterion for choosing the equation of best fit in the one-dimensional analysis was the standard error of estimate.

This was defined by

$$s = \left[\frac{\sum_{e=1}^n (D_e - D)^2}{n - q} \right]^{1/2},$$

where D_e is the experimental value of the diffusion coefficient at each temperature, D is the value calculated from the least squares equation at the same temperature, n is the number of experimental data points, and q is the number of coefficients in the fitting equation. The standard error of estimate was computed from the residuals in the least-squares routine.

4. Value Judgments

Precision

Estimates of precision were based on standard error of estimate analysis. The standard error of estimate is the end result of a statistical analysis of the numerical data, and the statistical analysis depends on various factors, such as the number of the data points, the nature of the concentration dependence, and the temperature dependence of the particular physical property.

The precision is defined here as the standard error expressed as a percent value. Assuming a normal distribution, about 68% of the data points lie within this estimate of precision, 95% within twice this value, and approximately 99% within three times this value. Where the preceding approach was not possible, we refer to the published error estimate of the original authors.

Accuracy

Accuracy estimates were based on assessments of experimental details including method of measurements, techniques, analytical characterization of chemicals, and intercomparisons with results from the same and/or different laboratories. The accuracy estimates are more subjective than the estimates of precision.

5. Experimental Techniques

For basic principles and practice in diffusion measurements, see [10-12]. For fused salts, the various methods may

be collected under two broad headings, namely electrochemical and analytical-transport, i.e.:

Electrochemical methods

- chronopotentiometry
- chronoamperometry
- linear sweep voltammetry
- polarography
- rotating disc electrode
- faradaic impedance

Analytical-transport coupled methods

- interferometric method
- capillary method
- porous frit technique
- diffusion couple method
- diaphragm cell
- gravimetric technique
- chromatographic method
- cylindrical thin layer method

Other

- NMR line width technique
- conductance method

A brief description of the basic principles for each technique as applicable to molten salts measurements follows herewith.

Electrochemical Methods

For a review of the various electrochemical techniques as used in molten salt systems, see Lesko [13].

Chronopotentiometry. Chronopotentiometry has been most widely applied for the determination of diffusion coefficients in fused salts. Basically, a constant current electrolysis of a dilute solution is carried out and the variations in the potential of the indicator electrode, against a suitable reference, are monitored as a function of time. The time span between the onset of electrolysis and when the depolarizer concentration at the electrode surface becomes zero is called the transition time. For the case where the mass transport is controlled by semi-infinite linear diffusion, the transition time is related to other experimental parameters by the Sand equation:

$$D = \left[\frac{4\tau I^2}{\pi n^2 F^2 A^2 C_0} \right] \quad (7.1)$$

where τ is the transition time (s), I is the constant electrolysis current (A), n is the number of electrons involved in the electron transfer step, F is the Faraday constant (C mol⁻¹), A is the area of the indicator electrode (cm²), C_0 is the concentration of the depolarizer in the bulk of the solution (mol cm⁻³), and D is the diffusion coefficient (cm² s⁻¹).

Diffusion coefficients of the electroactive species may be calculated from equation 7.1. For further details of chronopotentiometry, see [15, 16, 18-20]. It has been shown by Laity and McIntyre [14], that the chronopotentiometric diffusion coefficient of an ion is identical to both the interdiffusion and self-diffusion coefficients for dilute molten salt solutions.

In recent work it has been shown that the above restriction to dilute solute ions is not limiting. Thus Braunstein et al. [279, 280, 282], through a rigorous theoretical examination of the basic principles, have derived equations and computational methods which extend the chronopotentiometric

technique for the determination of diffusion coefficients in the concentrated solution range. The diffusion data for Be^{2+} in LiF-BeF_2 mixtures (95 mol% BeF_2), were thus determined (see system 67).

Chronoamperometry. In chronoamperometry a potential-step function is applied to the working electrode and the resulting current is measured as a function of time. The potential step is selected such that at the initial potential no faradaic current flows, and at the final potential the current is diffusion limited. For semi-infinite linear diffusion control the instantaneous current, I_t , is given by the Cottrell equation:

$$I_t = \left[\frac{nFAD^{1/2}C_0}{\pi^{1/2}t^{1/2}} \right] \quad (7.2)$$

where t is the time (s), and the other terms have the same significance as described earlier. From the above equation it is apparent that the product $I_t t^{1/2}$ is constant. Diffusion coefficients of the electroactive species can be evaluated from equation (7.2). Values of the correction factor to be applied to equation (7.2) for diffusion toward spherical and cylindrical electrodes have been tabulated by Bansal and Plambeck [17]. For greater details of this technique references [16], [19–20] may be consulted.

Linear Sweep Voltammetry. For linear sweep voltammetry, a rapidly changing ramp potential ($> 10 \text{ mV s}^{-1}$) is applied to the indicator electrode, and the resulting current is measured as a function of this potential. The solution is unstirred and mass transport is diffusion controlled. The current increases to a maximum and then decays, yielding a peak shaped curve. The peak current, I_p , for a reversible system is given by the Randles-Sevcik equation:

$$I_p = \left[\frac{0.447(nF)^{3/2}AC_0D^{1/2}V^{1/2}}{(RT)^{1/2}} \right] \quad (7.3)$$

where V is the voltage sweep rate (V s^{-1}), R is the gas constant, T is the temperature (K), and other terms have the same meaning as above. From the above equation it is clear that $I_p V^{-1/2}/C_0$ should be constant, and values of the diffusion coefficient may be calculated from equation (7.3). For further details of rapid scan voltammetry, see references [16], [18–20].

Polarography. Polarography is an electrochemical technique in which the current flowing at a dropping mercury electrode (dme) is measured as a function of the applied potential. The current-potential plot is known as the polarogram. The current corresponding to the plateau of the wave is the diffusion current.

The instantaneous faradaic current at any time during the life of the drop is given by the Ilkovic equation:

$$I(t) = [708nD^{1/2}C_0m^{2/3}t^{1/6}] \quad (7.4)$$

where $I(t)$ is the current (μA) at any time t since the beginning of the drop formation, n is the number of electrons involved in the reduction or oxidation of the electroactive species, C_0 is the bulk concentration (mmol L^{-1}), m is the rate of flow of mercury (mg s^{-1}), and other terms have the conventional significance. (If $t = t_d$, i.e., the drop time of the dme, then the value of current obtained from the above equation is the maximum diffusion current obtained during the drop life).

The mean diffusion current is obtained by integrating $I(t)$ with respect to time over the total drop life and then dividing by the drop time, t . Thus the Ilkovic equation for the mean diffusion current becomes:

$$I_d = [607nC_0D^{1/2}m^{2/3}t_d^{1/6}] \quad (7.5)$$

where I_d is the average current, t_d is the drop time and other terms are the same as defined above. The diffusion coefficients may be evaluated from equation (7.5). In the higher temperature range, the dme cannot be used because of the high vapor pressure of mercury. Dropping electrodes of other metals, Bi, Pb, Zn, have been tried. For additional information, see [16], [18], [20], and [21].

Rotating Disc Electrode. The presence of natural convection complicates the study of electrode processes at stationary electrodes. Forced convection, however, may be used to advantage as a mass transport process. Under forced convective mass transport, a steady-state current is observed, i.e., the current is independent of time. These conditions are achieved by rotating electrode technique.

The limiting current at a rotating disc electrode is given by Levich equation [22, 23]:

$$I_L = [0.62nFAD^{2/3}C_0\nu^{-1/6}\omega^{1/2}] \quad (7.6)$$

where I_L is the limiting current (A); $\omega = 2\pi f$ is the angular velocity of the disc, f is the number of rotations per second; ν is the kinematic viscosity ($\text{cm}^2 \text{s}^{-1}$) of the solution, and the other quantities are the same as before. The kinematic viscosity is the viscosity of the solution divided by its density. When the viscosity is in poise ($\text{g cm}^{-1} \text{s}^{-1}$) and the density in g cm^{-3} , the kinematic viscosity is in units of $\text{cm}^2 \text{s}^{-1}$. The above equation, thus, is used to obtain the values of D for electrochemically active species. See [16, 22, 23] for additional details.

Faradaic Impedance. This technique has found most applications to reactions in aqueous solutions and was first applied to molten salt systems by Laitinen and coworkers [24, 25].

Under conditions where the electrode impedance is determined entirely by the discharge and diffusion of ions, the resistive and capacitative impedances of the electrode (R_f , C_r , respectively), are linearly related to $f^{-1/2}$, i.e.:

$$R_f = \left[R' + \frac{b}{\sqrt{f}} \right] \quad (7.7)$$

and

$$\left(\frac{1}{\omega C_r} \right) = \left(\frac{b}{\sqrt{f}} \right) \quad (7.8)$$

where f is the frequency of the ac signal (Hz), $\omega = 2\pi f$, and R' and b are given, respectively, by (RT/nFi) and $(RT/n^2F^2AC_0\pi^{1/2}D^{1/2})$, and i is the exchange current. From measurements of R_f and C_r over a series of f , the value of the diffusion coefficient of the potential determining ion, D , is gained from the above equations.

For additional details see [18, 19, 26–32].

Advantages and Limitations. From a consideration of the molten salts diffusion literature (> 760 publications), it is apparent that approximately 75% of the diffusion data were obtained by the preceding electrochemical techniques. A comparison of the frequency that specific electrochemical techniques have been used is summarized in table 4. Inspec-

tion shows that the chronopotentiometric technique, by far, has seen widest application for molten salts diffusion data.

Some of the advantages and limitations of the electrochemically based techniques may be summarized as follows.

The electrochemical methods are quite rapid compared to other techniques. This is of greatest significance for systems where the values of diffusion coefficients are small ($\sim 10^{-6}$ to $10^{-8} \text{ cm}^2 \text{ s}^{-1}$). The technique, thus, appears suitable for studies in which the measurements are to be extended into the metastable supercooled region (KNO_3 - $\text{Ca}(\text{NO}_3)_2$) or highly viscous melts (BeF_2 , ZnCl_2 containing melts).

The diffusion data available from electrochemical experiments are frequently affected by the nature of the electrode reactions and by variations of the effective area of the working electrode.

The diffusion species must be electroactive to be sensed by the electrochemical approach, and the oxidation or reduction of the species must be possible within the potential span of stability of the solvent system. The electrode process should be clearly understood and the mass transport should be diffusion-controlled.

Analytical-Transport Coupled Methods

Some of the salient principles of the various methods in this category, together with the working equations, are briefly examined. The advantages and limitations of each method are assessed, and an analysis of the frequency of use (based on this study) is also reported.

Interferometry. Interdiffusion coefficients are measured by recording the phase variations introduced on an initially plane wave front when passing through a diffusion cell. The path differences are observed by wave front-shearing interferometry. The variations of refractive index in the test region thus monitored enable one to investigate processes directly related to a density gradient, such as diffusion. The theory and practice of this technique are well established at ambient temperatures ($\sim 25^\circ\text{C}$), and the extension to high temperatures awaited the work by Gustafsson et al. [33-42]. For experimental details, i.e., the design of light channels into the hot zone, and the (stainless steel) diffusion cells, see [33, 34]. With appropriate cell dimensions, and relatively small shears, it has been shown [40] that the working equation reduces to:

$$D = [0.10857(x_i^2 - x_j^2)/[t \log_{10}(x_i/x_j)]] \quad (7.9)$$

where x_i and x_j are the positions of the two fringes having identical path difference values, and t is the time.

Capillary Technique. Two variations of this technique

TABLE 4. Percent application of electrochemical diffusion techniques in molten salts measurements.

Experimental technique	% Application
Chronopotentiometry	44
Linear sweep voltammetry	11
dc polarography	5
Rotating disc electrode	5
Chronoamperometry	3
Faradaic impedance	2
Others	3

have been developed for molten salts studies: (i) diffusion out of the capillary, and (ii) diffusion into the capillary. The working equations, based on solutions of Fick's second law of diffusion are as follows:

(i) "diffusion out of"

$$D = \left[\frac{4L^2}{\pi^2 t} \ln \left(\frac{8}{\pi^2 \Delta} \right) \right] \quad (7.10)$$

and

$$D = (0.7854(1 - \Delta)^2 L^2 / t) \quad (7.11)$$

for $\Delta < 0.4$ and $\Delta > 0.5$, respectively. Here Δ is the ratio $(C_f - C_0)/(C_r - C_0)$, and C_f is the final mean activity within the capillary; C_r is the reservoir activity, and C_0 is the bath activity (which is constant). The length of the capillary is L , and t , the diffusion time. The diffusion equations, above, are accurate to $\sim 0.2\%$ and $\sim 0.3\%$, respectively [43, 44].

(ii) "diffusion into"

$$Q = [2C_0 A (Dt/\pi)^{1/2}] \quad (7.12)$$

where Q is the total diffusate after time t , C_0 the constant bath concentration, and A , the capillary cross-sectional area [45-49].

For details on experimental assemblies, and capillary filling techniques see [43-55]. The "diffusion out of" appears to be more accurate than the "diffusion into" variation of the capillary methods [53]. Additional observations on the limitations follow later in this work.

Porous Frit Technique. This modification of the capillary method was advanced by Djordjevic and Hills [56] so that the diffusion times could be reduced drastically. Instead of a single capillary, a fritted disc (which can be regarded as composed of many small, irregularly shaped capillaries) is employed.

This porous frit is impregnated with the active species so that diffusion occurs from both disc faces. The diffusion coefficient D , of the active species is calculated from:

$$D = (D' \phi) \quad (7.13)$$

where ϕ is the porous frit labyrinth constant, and D' , the apparent diffusion constant is obtained from the concentration of the diffusate \bar{c} in the frit after the time, t , of the measurements and the thickness, L , of the frit, viz:

$$\bar{c} = \left\{ \frac{8C_0}{\pi^2} \sum_{n=0}^{n=\infty} \frac{1}{(2n+1)^2} \times \exp \left[\frac{-(2n+1)^2 \pi^2 D' t}{L^2} \right] \right\} \quad (7.14)$$

If $D' t / L^2 > 0.2$, the series expansion in (7.14) converges so rapidly that only the first term of the series needs to be considered.

For details on the experimental assemblies used with molten salts, labyrinth constant calibration, and related procedural aspects see [53, 56-59]. For use of the porous frit with gravimetric analysis, see later.

Diffusion Couple Method. In this technique, two columns of fluids are "coupled" in the diffusion capillary through a "vanishing bubble" technique so that the boundary is sharply defined at the meniscus of the lower column. On completion of the measurements, the capillary is broken at this junction "in situ," and the total diffusate in the upper part is determined by standard radiochemical methods. The

method has been used for molten oxides [61, 62] and was adapted for molten salts diffusion studies by Angell and Bockris [63, 64] both in theory and practice. The diffusion equation:

$$D = [\phi^2 \pi / (C_0^2 A^2 t)] \quad (7.15)$$

requires the measurement of ϕ , the total diffusate in the originally inactive sample; t , the diffusion time; A , the capillary cross section area; and C_0 , the initial radioactivity of the active sample.

Some of the negative features (lack of definition of boundary; volume change on quenching) were removed by the innovations of Angell and Bockris (vanishing bubble and *in situ* termination techniques); for details on filling techniques and experimental procedures see [63–65].

Diaphragm Cell Method. This technique is basically one of the simplest for diffusion measurements and has been widely used at ambient temperatures. The working equation, after Gordon [66] and Stokes [67], is:

$$\ln \frac{\Delta C_0}{\Delta C_t} = \left[\frac{1}{\beta} \left(\frac{1}{V_A} + \frac{1}{V_B} \right) D t \right] \quad (7.16)$$

where ΔC_0 and ΔC_t are the difference in the concentrations on either side of the porous diaphragm at the initial and termination times; V_A and V_B are the volumes of the liquids; D , the diffusion coefficient; and β , the diaphragm cell constant. An underlying principle is that if V_A and V_B are relatively large volumes, and only a small amount of solute diffuses, the difference in concentration may be taken as constant, so that the conditions across the diaphragm are essentially those for steady state diffusion. For experimental assemblies, theory, and practice, see [68, 69], and for molten salts assemblies see [70, 73].

Gravimetric Diffusion Technique. In this technique, an analytical balance is used to monitor the buoyancy change of the porous frit immersed in the molten salt mixture from an under the pan suspension. The porous frit is initially saturated with the one of the molten salt mixtures. The buoyancy changes due to interdiffusion are followed as a function of time. The principles have been described in detail elsewhere [74–77], and were adapted for high temperature measurements with molten salts by Sjöblom [75, 76, 78].

The values of diffusion constant, D , are gained from:

$$[d [\log_{10}(w_t - w_\infty)]/dt] = -D/k \quad (7.17)$$

where w_t and w_∞ are two apparent porous frit weights at times t , and the final time (∞), and k is the porous frit cell constant. The latter is generally gained by an ancillary calibration experiment using a system for which the D values are known as reference values. For some additional considerations of the porous frit shapes, and the limitations of eq. (7.17), see [79, 80]. See also [510].

Chromatographic Technique. In adapting the techniques of paper-strip chromatography to molten salts systems, asbestos strips [80, 81], glass-fiber matte on glass plates [82, 83], quartz fiber matte and alumina [84–88], thin layer of porous ceramic oxides (Al_2O_3 , MgO , ZrO_2) [89–92], and sintered MgO strips [93] have been used to hold the molten system. The sample is tagged with a suitable radioisotope by pressing a second small strip with the tracer in the impregnated strip briefly. On completion of the diffusion period, the

activity is monitored by the conventional radiochemical techniques after the system is (rapidly) brought to room temperature. The impregnated substrate minimizes volume change corrections in this procedure. For additional experimental details, see [80, 82, 83, 86, 87, 89, 93].

The solution of Fick's law of diffusion under the boundary conditions imposed by the above procedures [81, 82, 93] leads to the expression:

$$C_i(x) = \frac{C_i}{(\pi D t)^{1/2}} \times \exp[-x^2/(4 D t)] \quad (7.18)$$

Accordingly, the values of D_i are determined from the slope of $\log C_i(x)$ vs x^2 . Here $C_i(x)$ and C_i are the specific activity at the distance x after time t , and the total activity of the diffusate.

The expansivity of MgO is low (~1% from 25–800 °C), and MgO is one of the most stable oxides. With this technique and the sintered porous MgO self-supporting substrates, diffusion in highly aggressive chloride and fluoride melts has been investigated [93].

Cylindrical Thin Layer (CTL) Method. In this technique, a thin layer of melt is held by two close fitting axially concentric graphite crucibles. Under the conditions of the experiment, eq. (7.17) holds, and the tracer diffusion coefficients are gained accordingly. For details see [93]. The technique was developed for tracer diffusion studies, especially for fluoride melts.

Advantages and Limitations. As indicated earlier, about 25% of the molten salts diffusion data surveyed in this study was gained by the preceding techniques, i.e. the non-electrochemical techniques. The frequency of use in molten salts is summarized in table 5; it is clear that the capillary techniques, and a modification thereof, namely the porous frit method, account for ~80% of the diffusion data from this group.

Some of the advantages and limitations of these methods should be noted as follows:

Interferometry. The advantages appear to be: the duration of each run of diffusion experiment is short (~1 h); the interferograms can be continuously monitored; the absence of convection can be directly confirmed through the fringes; the diffusion process can be studied *in situ*, i.e., without disturbing or interrupting the process under study; diffusion coefficients can be calculated from pairs of fringes, and the final value of diffusion coefficient can thus be evaluated by statistical treatments.

The salient limitations are the restriction to optically transparent liquids having large variations of refractive in-

TABLE 5. Percent application of analytical-transport coupled diffusion techniques in molten salts measurements

Experimental techniques	% Application
Capillary techniques	67
Chromatography method	7
Interferometry method	7
Porous frit techniques	13
Others	6

dex with composition and temperature. Most of the fused salts meet these requirements. The upper temperature is limited by optical disturbances due to thermal radiation from the melt; it may be possible to extend the measurements to ~1000 °C.

Capillary Techniques. Diffusion periods > 6 h are required for a good degree of accuracy; the duration of the experiments increases greatly for viscous systems. In general the capillary techniques are not suitable for systems having only short-lived radioactive isotopes. For the "diffusion into the capillary" method, the times are relatively short by comparison (1–3 h); this approach, however, requires relatively larger amounts of radioactivity and also, is judged to be less accurate than the "diffusion out of the capillary" technique [18].

The "immersion effect," should be noted as a possible error source. This effect refers to the tendency to sweep out part of the active solution from the capillary in the act of immersion or removal. This error source is minimized if the diffusion times are long, and also if a drop of solution is retained on the capillary just prior to immersion. For additional information see [124, 126–127].

An additional possible error source, referred to as the " ΔL -effect," is the effect of the rate of stirring; if the rate is too rapid, this leads to D values too large; if it is too slow, this error source leads to D values too low. For diffusion times > several hours, the errors due to this effect are quite small. See [10, 12, 43, 46, 123–125] for details.

Porous Frit Technique. The porous frit technique does not seem well suited for comparatively high self-diffusion coefficients. For example the values for Na^+ and CO_3^{2-} in molten carbonate by this technique are too large (~ $\times 10 \sim \times 20$); the contributing factors are not understood since the porous frit technique has reproduced D values at ambient temperatures. An advantage of this technique is the relatively short times required; it is thus well suited for measurements with isotopes of short-half lives, e.g., ^{82}Br (~30 minutes). It also seems well suited for the more viscous salts, e.g. molten ZnCl_2 , for which the times with the simple capillary technique would be prohibitively long. See also: Gravimetric Technique.

Diffusion Couple Technique. The technique requires a great deal of manual dexterity. The main sources of error lie in a small but irreproducible dilution of the radioactive column during the filling process, and statistical uncertainties in the activity analysis. An advantage is that the " ΔL -effect" and the "immersion effects" of the simple capillary method are avoided.

Diaphragm Cell Technique. This technique has seen only very limited applications with molten salts. It is a relative technique since the diaphragm pore area and length cannot be determined in an absolute manner.

Gravimetric Technique. If the porous frits are made of glass rather than quartz, this technique is not reliable owing to the relatively rapid ion-exchange. Thus while the diffusion coefficients for mono-valent cations into pyrex are relatively low (~ $10^{-11} \text{ cm}^2 \text{ s}^{-1}$ @ ~300 °C) the large melt-frit interface leads to a significant ion-exchange during the gravimetric measurements.

Chromatographic Method. The advantages appear to be

in simplicity. The end effects (of the capillary methods) are inherently absent. No special apparatus is required and the technique appears suited for measurements under difficult conditions, e.g., as in high pressure vessels.

A limitation is in the relatively large area of melt that is exposed; thus the method appears limited to systems with low vapor pressure. A further problem is in the need to impregnate the chromatographic strip uniformly; non-uniform impregnation leads to irreproducibilities of D values.

Cylindrical Thin Layer (CTL) Techniques. This variation of the capillary method appears suited for corrosive molten salts (e.g. fluorides), and for systems with relatively high vapor pressure. The salient error sources appear in the possible convection in the capillary, and the contraction during freezing (termination of measurements). For additional details see [93].

Other Methods

Two additional methods, as below, are to be noted relative to molten salts.

NMR Line Width Technique. This method has been used for some preliminary diffusion measurements in solid and molten salts, e.g., LiI [510]. The line width of the nuclear magnetic resonance (NMR) line is determined as a function of temperature. Both pulsed and steady state NMR have been used, mainly in studies of ionic crystals and metals, but also in some cases, of molten salts. The diffusion coefficients are calculated from the basic equation:

$$\frac{1}{\nu_i} = \frac{d^2}{6D_i} \quad (7.19)$$

expressing the relationship between the jump frequency, ν_i , the diffusion coefficients, D_i , and d , the jump distance or next-nearest neighbor distance in the ionic crystal. Reduction to the practical expression follows from Torrey's model of ionic diffusion [511]. It is to be noted that no macroscopic diffusional flow is measured. For details, see [510].

Conductance Method. This method uses the principles of ionic dilute solution theories to calculate the diffusion constants. Thus the Nernst-Einstein equation, relating the diffusion constant, D_i , and the equivalent ionic conductance, λ_i , is used in the form:

$$D_i = H_R (RT\lambda_i/z_i F^2) \quad (7.20)$$

where H_R is the Havens correlation factor for ionic conductors [512], and λ_i is gained from equivalent conductance data and transport numbers in the conventional manners. For additional details, see [510].

Advantages and Limitations. For these two methods, the following aspects are to be noted.

In the NMR technique, the calculation of the spin relaxation times (from the line width measurements) is limited by various problems, such as line shapes, quadrupole interactions, and magnetic field inhomogeneities.

In the conductance method, the use of the Nernst-Einstein equation implies conditions under which the ionic mobilities are independent of each other (as in infinitely dilute electrolytes). Application of this equation to molten salts is also subject to further uncertainties relative to values for the

Havens correlation factor and of transport numbers in molten salts. An uncertainty of $\sim \pm 10\text{--}20\%$ has been advanced for the thus estimated values for D_i [510].

6. Intercomparisons of Diffusion Techniques

For three systems the number of investigations appears sufficient to enable meaningful intercomparison, viz.,

(a) for the self-diffusion of Na^+ in molten NaNO_3 , some 21 independently conducted studies, by 4 different techniques.

(b) for the diffusion of Ag^+ in molten NaNO_3 , some 11 independently conducted studies, by 7 different techniques.

(c) for the diffusion of Cd^{2+} in the molten LiCl-KCl eutectic, some 14 independently conducted studies, by 5 different techniques.

The results are illustrated in figures 1-3 and tables 6-8 here-with. Some observations thus possible, are as follows.

$\text{Na}^+/\text{NaNO}_3$: The agreement between the values from all four techniques (diffusion out of capillary, diffusion into capillary, chromatography, porous frit) is $\sim \pm 10\%$. The values from five different laboratories, each using the "diffu-

sion out of the capillary" technique fall closely together ($\sim \pm 1.5\%$). Based on the preceding, the value for D_{Na^+} is recommended as:

$$D_{\text{Na}^+} = 2.30(\pm 0.03) \times 10^{-5} \text{ cm}^2 \text{s}^{-1}. \quad (7.21)$$

at 350 °C in molten NaNO_3 .

$\text{Ag}^+/\text{NaNO}_3$: The agreement of the D values determined by chronopotentiometry, rapid scan voltammetry, porous frit, and interferometry leaves little to be desired.

The techniques of the diaphragm cell, linear diffusion cell, and gravimetric frit, apparently yield values for D that are lower.

Based on the preceding, the value for D_{Ag^+} is recommended as:

$$D_{Ag^+} = 2.60(\pm 0.2) \times 10^{-5} \text{ cm}^2 \text{ s}^{-1} \quad (7.22)$$

in molten $NaNO_3$ at 350 °C.

$Cd^{2+}/LiCl-KCl$: Inspection shows that, with the exception of some four values, the D values determined by the techniques of capillary, chronopotentiometry, linear sweep voltammetry, dc polarography, and faradaic impedance, are in close agreement. Four values, as noted, may be dismissed as inaccurate.

For $D_{Cd^{2+}}$ the value of:

$$D_{Cd^{2+}} = 1.60(\pm 0.20) \times 10^{-5} \text{ cm}^2 \text{ s}^{-1} \quad (7.23)$$

in molten $LiCl-KCl$ is recommended at 450 °C.

Accuracy estimates for the various measurement methods are given as part of the diffusion data tables.

7. Classification of Diffusion Solvents and Diffusing Species

Solvents

For the arrangement of the various single and multi-component salt systems used as solvents in the diffusion measurements, the "anion family" classification of the molten salt data series [1-9] has been used. This classification is organized as follows.

Within an anion family, the salts are listed according to increasing valency of the cation; e.g., MX , MX_2 , MX_3 , MX_4

Within a category, the salts are listed according to the position of the cation in the periodic table of elements.

Mixtures are listed according to increasing number of components, i.e., binary, ternary....

Mixtures with common anions; the systems are ar-

ranged according to positions of the cations in the periodic table of elements. Also the order: mono-monovalent, mono-divalent, mono-trivalent, di-divalent... has been followed.

Mixtures with dissimilar anions: these are listed under "others." However, mixed halides are listed as a separate category.

The different anion families have been ordered according to the increasing number of atoms present in the anion. Different anions with the same number of atoms are arranged according to alphabetical order of their chemical formula, e.g., CO_3 , NO_3 , PO_3 .

Sulfur and polysulfides are listed together as a separate category.

Diffusing Species

An alphabetical order according to the elemental symbol and/or chemical formula of the species was adopted for listing the diffusing species.

8. Diffusion Data Tables

For each system the results are reported as follows:

System number and formula(e)

List of diffusing species

Diffusion equation

Measurement techniques, estimate of uncertainties, and diffusing species

Diffusion equation parameters, temperature ranges, and precisions

Diffusion coefficients: numerical values

Diffusing species and literature references number.

Where two or more studies are cited, the underscore indicates the recommended study.

Literature reference citations

The molten salt systems and the diffusing species are cross-indexed in two summarizing tables.

System 1. LiF

List of diffusing species studied in LiF as solvent

Table 1.1. Diffusion technique, uncertainty, and species

Diffusion technique of recommended study	Uncertainty (in values of D)	Species
conductivity	$\sim \pm 10\text{-}20\%$	Li^+ [510]
molecular dynamics	$\sim \pm 50\%$	Li^+, F^- [129,130]

Table 1.2. Self-diffusion coefficients

Species	T (K)	$D_{\text{Li}^+} \times 10^5$ ($\text{cm}^2 \text{s}^{-1}$)	References	Species	T (K)	$D_{\text{Li}^+} \times 10^5$ ($\text{cm}^2 \text{s}^{-1}$)	References
Li^+	1215	18	129	F^-	1215	9.0	129
	1287	13.6	130		1287	11.3	129

Values of D are calculated from molecular dynamics [129,130]. At 1124K the value for D_{Li^+} from conductivity is estimated as $12.2 \times 10^5 \text{ cm}^2 \text{s}^{-1}$ [510].

System 2. NaF

List of diffusing species investigated in NaF as solvent

The italicized species indicate studies with insufficient data-sets for characterization of temperature dependence of diffusion coefficients. For these species: see table 2.4.

System 6. NaBF_4 List of diffusing species investigated in NaBF_4 as solvent

Table 6.1. Diffusion technique, uncertainty, and species

Diffusion technique of recommended study	Uncertainty (in values of D)	Species
chronopotentiometry & rapid scan voltammetry	$\sim \pm 50\%$	Ti^{4+}

Table 6.2. Diffusion coefficients

Species	T (K)	$D \times 10^5$ ($\text{cm}^2 \text{s}^{-1}$)	References
Ti^{4+}	693	0.2 ^a	138

^aAverage of values obtained by two techniques.

System 7. Na_3AlF_6 List of diffusing species investigated in Na_3AlF_6 as solvent

The italicized species indicate studies with insufficient data-sets for characterization of temperature-dependence of diffusion coefficients. For these species: see table 7.4.

Table 7.1. Diffusion techniques, uncertainties and species

Diffusion technique of recommended study	Uncertainty (in values of D)	Species
capillary	$\sim \pm 20\%$	Na^+, F^-
chronopotentiometry	$\sim \pm 20\%$	Ta(V)
double-layer impedance	$\sim \pm 20\%$	CO_2
rotating disc electrode	$\sim \pm 20\%$	Al_2O_3

Equation:

$$D = A \exp[-E/RT] \quad (7.1)$$

precision: in table 7.2 uncertainty: in table 7.1

Table 7.2. Parameters of diffusion equation (7.1), precisions, and references

Species	$A \times 10^3$ $(\text{cm}^2 \text{s}^{-1})$	E (cal mol $^{-1}$)	Temp. range (K)	Precision	References
Na^+	4.58	10200	1307-1338	$\pm 2.2\%$	140
F^-	0.877	7106	1307-1338	$\pm 1.3\%$	140

Table 7.3. Self diffusion coefficients, $D \times 10^5$ ($\text{cm}^2 \text{s}^{-1}$), from equations in table 7.2

T (K)	Na^+	F^-
1310	9.10	5.72
1320	9.37	5.84
1330	9.65	5.96
1340	9.93	6.08

System 7. Na_3AlF_6 (cont'd)

Table 7.4. Diffusion coefficients for species not included in table 7.3

Species	T (K)	$D \times 10^5$ (cm^2s^{-1})	References
Ta(V)	1273	7.0	139
Al_2O_3	1323	2.0(a)	141,142
^{26}Al	1324	6.9	144,148
^{26}Al	1325	6.77	144,148
CO_2		0.005(b)	145,147

(a) This value is a merge of the results reported by Desclaux and Rolin[141], Thonsted[518], and Shurygin et al.[143,146,149]. The values reported were, respectively:[141] 1050°C , $2.7 \times 10^{-5} \text{ cm}^2\text{s}^{-1}$; [518] 1020°C , $1.5 \times 10^{-5} \text{ cm}^2\text{s}^{-1}$; [143,146,149] 1050°C , $1.33 \times 10^{-5} \text{ cm}^2\text{s}^{-1}$, respectively.

(b) This value is based on a solubility of CO_2 in molten cryolite of $\sim 5 \times 10^{-6}$ mole cm^{-3} at 1000°C .

System 8. LiCl List of diffusing species investigated in LiCl as solvent

Table 8.1. Diffusion techniques, uncertainties, and species

Diffusion technique of recommended study	Uncertainty (in values of D)	Species
capillary	$\sim \pm 20\%$	$\text{Li}^+, \text{Cl}^-, \text{Na}^+, \text{Rb}^+, \text{Cs}^+$
chronopotentiometry	$\sim \pm 10\%$	$\text{Pb}^{2+}, \text{Ag}^+, \text{Zr}^{2+}, \text{Mo}^{3+}$
Faradaic impedance	$\sim \pm 50\%$	Cl_2

Equation:

$$D = A \exp[-E/RT] \quad (8.1)$$

precision: in table 8.2 uncertainty: in table 8.1

System 8. LiCl (cont'd)

Table 8.2. Parameters of diffusion equation (8.1), precisions, and references

Species	$A \times 10^3$ ($\text{cm}^2 \text{s}^{-1}$)	E (cal mol $^{-1}$)	Temp. range (K)	Precision	References

820	12.27	930	27.72
830	13.33	940	29.57
840	14.45	950	31.51
850	15.64	960	33.52
860	16.90	970	35.62
870	18.23		

For molten Li at 742 K, the value for D_{Li^+} , from conductivity and NMR techniques, are: 11.0×10^{-5} and $3.11 \times 10^{-5} \text{ cm}^2 \text{s}^{-1}$, respectively. The former approximates closely the values gained from tracer diffusion techniques (~± 10-20%); the NMR value suggests an anomalous effect, and may be understood if part of the lithium ions in Li behave as super-conductors [510].

System 31. NaI

System 32. KI

List of diffusing species investigated in KI as solvent

The italicized species indicate studies with insufficient data-sets for characterization of temperature-dependence of diffusion coefficients. For these species: see table 32.4.

Table 32.1. Diffusion techniques, uncertainties, and species

Diffusion technique of recommended study	Uncertainty (in values of D)	Species
chronopotentiometry	$\sim \pm 20\%$	I_2
not cited	$\sim \pm 50\%$	Ti^+, Ag^+

Equation:

$$D = A \exp[-E/RT] \quad (32.1)$$

precision: in table 32.2

uncertainty: in table 32.1

Table 32.2. Parameters of diffusion equation (32.1), precision, and references

Species	$A \times 10^3$ ($\text{cm}^2 \text{s}^{-1}$)	R (cal mol $^{-1}$)	Temp. range (K)	Precision	References
I_2	178.18	14964	970-1120		214

No entry in precision column indicates estimates not possible since results were reported as equations only.

Table 32.3. Diffusion coefficients, $D \times 10^5$ ($\text{cm}^2 \text{s}^{-1}$), from equation in table 32.2.

T (K)	I_2	T (K)	I_2
970	7.57	1050	13.68
990	8.86	1070	15.65
1010	10.30	1090	17.80
1030	11.90	1110	20.16
1040	12.77	1120	21.42

Table 32.4. Diffusion coefficients for species not included in table 32.3.

Species	T (K)	$D \times 10^5$ ($\text{cm}^2 \text{s}^{-1}$)	References
Ti^+	720	3.1	209
Ag^+	720	4.6	209
	780	3.3	
	780	5.1	

System 33. CsI

List of diffusing species investigated in CsI as solvent

 I_2

Table 33.1. Diffusion technique, uncertainty, and species

Diffusion technique of recommended study	Uncertainty (in values of D)	Species
chronopotentiometry	$\sim \pm 20\%$	I_2

Equation:

$$D = A \exp[-E/RT] \quad (33.1)$$

precision: in table 33.2

uncertainty: in table 33.1

Table 33.2. Parameters of diffusion equation (33.1), precision, and references

Species	$A \times 10^3$ ($\text{cm}^2 \text{s}^{-1}$)	E (cal mol $^{-1}$)	Temp. range (K)	Precision	References
I_2	93.29	13591	970-1120		214

No entry in precision column indicates estimate not possible since results were reported as equations only.

Table 33.3. Diffusion coefficients, $D \times 10^5$ ($\text{cm}^2 \text{s}^{-1}$), from equation in table 33.2.

T (K)	I_2	T (K)	I_2
970	8.08	1050	13.83
990	9.32	1070	15.63
1010	10.69	1090	17.57
1030	12.19	1110	19.67
1040	12.99	1120	20.79

System 34. AgI

List of diffusing species investigated in AgI as solvent

 Ag^+, I^-

Table 34.1. Diffusion technique, uncertainties, and species

Diffusion technique of recommended study	Uncertainty (in values of D)	Species
porous frit	$\sim \pm 10\%$	Ag^+, I^-

Equation:

$$D = A \exp[-E/RT] \quad (34.1)$$

precision: in table 34.2

uncertainty: in table 34.1

System 34. AgI (cont'd)

Table 34.2. Parameters of diffusion equation (34.1), precisions, and references

Species	$A \times 10^3$ ($\text{cm}^2 \text{s}^{-1}$)	E (cal mol^{-1})	Temp. range (K)	Precision	References
Ag^+	1.206	5454	850-890	$\pm 2.1\%$	509
I^-	78470	24913	860-890	$\pm 0.2\%$	509

Table 34.3. Self-diffusion coefficients from equations in table 34.2.

T (K)	$D_{\text{Ag}^+} \times 10^5$	$D_{\text{I}^-} \times 10^5$	T (K)	$D_{\text{Ag}^+} \times 10^5$	$D_{\text{I}^-} \times 10^5$
850	4.78		880	5.33	5.10
860	4.96	3.66	890	5.52	5.98
870	5.14	4.33			

System 35. NaOH

List of diffusing species investigated in NaOH as solvent

Table 35.1. Diffusion technique, uncertainty, and species

Diffusion technique of recommended study	Uncertainty (in value of D)	Species
chronopotentiometry	$\sim \pm 20\%$	Bi^{3+}

	75	723	2.35	103
	90	723	2.34	103

For 10 mol % CsNO_3 , diffusion was investigated from 598 - 725 K. The data are expressed by the equation: $D = 0.794 \times 10^{-3} \exp[-4626/RT] \text{ cm}^2 \text{ s}^{-1}$; precision, $\sim \pm 1\%$; accuracy, $\sim \pm 5\%$. Within the limits of error, no difference in the values of D_{Cs^+} for this composition and that in pure NaNO_3 is observed.

G. J. JANZ AND N. P. BANSAL

System 140. $\text{Na}_3\text{AlF}_6\text{-Al}_2\text{O}_3$ (cont'd)

taining ions; the values of D in this study appear unusually high, i.e. $\sim 10^{-4} \text{ cm}^2 \text{s}^{-1}$ (by a factor of 10); a Grotthuss type mechanism is suggested to account for the increased translational mobility of the diffusing species.

(*) This value is based on a CO_2 solubility of $3.32 \times 10^{-6} \text{ mol cm}^{-3}$ [503]; with the earlier (less reliable) CO_2 solubility ($0.8 \times 10^{-7} \text{ mol cm}^{-3}$ [504]), D_{CO_2} is $\sim 12 \times 10^{-5} \text{ cm}^2 \text{s}^{-1}$.

System 141. KCl-NaPO_3 List of diffusing species investigated in KCl-NaPO_3 as solvent

Table 141.1. Diffusion techniques, uncertainties, and species

Diffusion technique of recommended study	Uncertainty (in values of D)	Species
rotating disk electrode	$\sim \pm 20\%$	$\text{Cu}^{2+}, \text{Cd}^{2+}, \text{Fe}^{3+}$

Table 141.2. Diffusion coefficients

Species	T (K)	$D \times 10^5$ ($\text{cm}^2 \text{s}^{-1}$)	References
Cu^{2+}	893	0.205	505
Cd^{2+}	893	0.665	505
Fe^{3+}	893	0.198	505

System 142. $\text{K}_2\text{SO}_4\text{-K}_2\text{S}_2\text{O}_7$ List of diffusing species investigated in $\text{K}_2\text{SO}_4\text{-K}_2\text{S}_2\text{O}_7$ as solvent

Table 142.1. Diffusion techniques, uncertainties, and species

Diffusion technique of recommended study	Uncertainty (in values of D)	Species
chronopotentiometry	$\sim \pm 20\%$	V^{5+}
chronoamperometry	$\sim \pm 20\%$	$\text{V}^{5+}, \text{O}_2$

System 142. $K_2SO_4-K_2S_2O_7$ (cont'd)

Table 142.2. Diffusion coefficients

Species	Melt composition (mol % K_2SO_4)	T (K)	$D \times 10^5$ (cm^2s^{-1})	References
V^{5+}	5.0	698	0.13	506
O_2	satd. with K_2SO_4	698	0.36	507

System 143. $Na_2O-SiO_2-B_2O_3$ List of diffusing species investigated in $Na_2O-SiO_2-B_2O_3$ as solvent

Table 143.1. Diffusion techniques, uncertainties, and species

Diffusion technique of recommended study	Uncertainty (in values of D)	Species
polarography	$\sim \pm 25\%$	$Cu^{2+}, Cd^{2+}, Fe^{3+},$ Co^{2+}, Ni^{2+}

Table 143.2. Diffusion coefficients

Species	T (K)	$D \times 10^5$ (cm^2s^{-1})	References
Cu^{2+}	1273	0.0032	247, 508
Cd^{2+}	1273	0.0044	247, 508
Fe^{3+}	1273	0.0091	247, 508
Co^{2+}	1273	0.0068	247, 508
Ni^{2+}	1273	0.0012	247, 508

9. List of Most Widely Investigated Systems

Table S-1. List of most widely investigated systems and references.

[The underscored reference is the data-base used for the recommended values]

System #	Solvent	Diffusing Species	References
9	NaCl	Na ⁺	43, <u>45</u> , 93, 123, 161, <u>162</u> , 165, 172, 175, 186

12. Acknowledgments

This work was made possible in large part by financial support received from the Office of Standard Reference Data, National Bureau of Standards, Washington, D. C. We wish to thank Lewis H. Gevantman (OSRD-NBS) for constructive suggestions and continued interest throughout the course of this work.
